ABSTRACT

Traditional yoghurt bacteria, Lactobacillus bulgaricus and Streptococcus thermophilus, usually do not survive under acidic conditions and bile concentrations when they encountered in the gastrointestinal tract. Therefore, for yoghurt to be considered as a probiotic product, probiotic bacteria are incorporated as a dietary adjunct. The purpose of this research was to produce acceptable yoghurt supplemented with indigenous probiotic bacteria. This research was divided into three parts i.e. addition of indigenous probiotic (Lactobacillus sp. Dadi13 and Lactobacillus plantarum Mut7) in standard formula, sensory evaluation of yoghurt on appearance, texture, flavor, and overall, and evaluation of selected probiotic culture for its viability and capability to grow with yoghurt starter. Lactobacillus sp. Dadi13 and Lactobacillus plantarum Mut7 were selected as indigenous probiotics cultures because they have the essential criteria for probiotic such as acid and bile tolerant, capable of suppressing enteric pathogenic bacteria, improving lactic acid bacteria population in colon and also have the ability to lower cholesterol levels. The results showed that Lactobacillus sp. Dadi13 produced better flavor compared with yoghurt supplemented with L. plantarum Mut7 and traditional yoghurt without probiotic supplementation. However, supplementation of Lactobacillus sp. Dadi13 produced lower sensory score on appearance, but similar in texture compared with traditional yoghurt. Supplementation of Lactobacillus sp. Dadi13 produced sensorically acceptable yoghurt and did not significantly different with traditional yoghurt. The number of total lactic acid bacteria (LAB) increased during fermentation from 2.45 x 10^7 CFU/ml to 2.31 x 10^8 CFU/ml. Combination of L. bulgaricus and S. thermophilus starter cultures produced highest lactic acid production. However, supplementation of Lactobacillus sp. Dadi13 did not statistically different on lactic acid production, pH, and LAB count. Supplementation of probiotic bacteria is important in order to make yoghurt have a better functional food properties.

Keywords: yoghurt, supplementation, indigenous probiotic, functional food

INTRODUCTION

Functional foods are foods with supposed to have specific health benefits. Probiotics are considered to be beneficial for health. Probiotics ("for life" in Greek) are live microorganisms, present in foods, which have a beneficial effect on the intestinal microbiota (Quillinien, 2001). According to Fuller (1989), probiotics are live microorganisms which actively enhance health of the host by improving the balance of microflora in the gut.
when ingested live in sufficient numbers.

Since lactic acid bacteria used for the manufacture of various fermented dairy foods such as yoghurt do not survive in the gastrointestinal tract, a trend today is to incorporate probiotic bacteria such as Lactobacillus acidophilus and bifidobacteria into fermented foods.

Traditionally, yoghurt is manufactured using Lactobacillus delbrueckii sp. bulgaricus and Streptococcus thermophiles. These yoghurt bacteria are claimed to provide some health benefits, but they do not survive under acidic conditions and bile concentrations as usual encountered in the gastrointestinal tract (Shah, 2001). Therefore, for yoghurt to be considered as a probiotics product, probiotics are incorporated as a dietary adjunct.

Fermented milk could be made with probiotics bacteria, but the quality is not as good as yoghurt made with traditional yoghurt bacteria. Yoghurt made with probiotics bacteria also need a longer fermentation process. Thus the normal practice is to make yoghurt with both yoghurt and probiotic bacteria.

Ngatirah et al. (2000) have studied the ability several strains of lactic acid bacteria isolated from several local sources in assimilating cholesterol and deconjugating bile salts. They found variation among those strains in the ability to assimilate cholesterol and deconjugate bile salts. Isolates which have the highest ability to assimilate cholesterol and deconjugate bile salts were Lactobacillus sp. Daid13 (isolated from traditional fermented buffalo milk) and Lactobacillus plantarum Mut7 (isolated from traditional fermented cassava). Therefore in this study, we used both isolates to be incorporated into yoghurt.

The purpose of this study was to produce an acceptable yoghurt supplemented with indigenous probiotic bacteria.

**MATERIALS AND METHODS**

**Strains and culture conditions**

Lactobacillus sp. Daid13, Lactobacillus plantarum Mut7, L. bulgaricus FNCC 0041, and Streptococcus thermophiles FNCC 0040 were obtained from Food and Nutrition Culture Collection, Center for Food and Nutrition Studies, Gadjah Mada University. Culture stocks were kept in 10% glycerol and 10% skim milk with the ratio 1:1, kept in sterile 1.5 mL polyethylene screw cap tubes, at -40°C. These strains were reinvoused in MRS broth (Merck, Oxoid) at 37°C for 24 h.

**Preparation of yoghurt**

Commercial pasteurized homogenized low fat milk and skim milk powder were used to make yoghurt. Commercial pasteurized homogenized low fat milk was added with skim milk powder, sucrose, and flavoring agent. The mixture was then pasteurized at 85°C for 30 min, cooled to 40°C prior to inoculation. The starter used was 10% of the total yoghurt mixture. Standard yoghurt was treated with different indigenous probiotics i.e. Lactobacillus sp. Daid13 and L. plantarum Mut7. The ratio of S. thermophiles and L. bulgaricus was 1:1, while S. thermophiles, L. bulgaricus, and Lactobacillus sp. Daid13 or L. plantarum Mut7 was 2:1:1. Enumerations of the Lactic Acid Bacteria were conducted before and after incubation at 43°C for 6-7 hours. Sensory evaluation was conducted on appearance, texture, and flavor by ten panelists to evaluate products acceptability.

**Co-culture of lactic acid bacteria**

To study whether Lactobacillus sp Daid13 can survive and compete with S. thermophiles and L. bulgaricus, single culture (S. thermophiles or L. bulgaricus or Lactobacillus sp. Daid13) and mixed cultures (S. thermophiles + L. bulgaricus; S. thermophiles + Lactobacillus sp Daid13; L. bulgaricus + Lactobacillus sp. Daid13; and S. thermophiles + L. bulgaricus + Lactobacillus sp. Daid13) were grown in 10% skim milk. Enumeration of the viable cells were conducted before and after incubation at 37°C for 18 h. Approximately 10 colonies of each plate were taken and observed under microscope for the morphological tests.
Enumeration procedures

Serial dilutions were prepared with dilution blanks composed of 0.1% peptone (Difco) in distilled water. The viable cells were counted using pour plates technique with MRS agar + CaCO₃. The MRS agar was prepared by dissolving 1.5% agar and 1% CaCO₃ in MRS broth prior to sterilizing (15 min at 121 °C). The plates were incubated at 37 °C for 48 h.

RESULTS

The yoghurt formulation was shown in Table 1. Addition of flavoring agent was addressed to obtain the more acceptable yoghurt formula by the unaccustomed consumers. From the three variations of yoghurt tested overall the best formula was obtained in yoghurt made with \( S. \) thermophilus and \( L. \) bulgaricus (control) with the overall score of 16, followed by yoghurt supplemented with \( L. \) acidophilus sp. Dad13 and the third was obtained in yoghurt supplemented with \( L. \) plantarum Mut7. \( Lactobacillus \) sp. Dad13 was isolated from fermented buffalo milk ("dahi") so it was more compatible to incorporated into yoghurt because it comes from the same inhabitant, while \( L. \) plantarum Mut7 was isolated from fermented cassava.

Sensory evaluations were conducted to know the differences in appearance, texture, and also flavors from 3 types yoghurt compared to commercial yoghurt. From Figure 1 it was shown that highest mean appearance score was in yoghurt made with \( S. \) thermophilus and \( L. \) bulgaricus. Followed by yoghurt supplemented with \( Lactobacillus \) sp. Dad13, Yoghurt supplemented with \( Lactobacillus \) sp. Dad13 did not significantly different compared to traditional yoghurt.

Figure 1. Sensory evaluation on appearance

Figure 2. Sensory evaluation on texture
Figure 2 indicated that highest average of texture score was obtained in yoghurt made with *S. thermophilus* and *L. bulgaricus*, and also yoghurt supplemented with *Lactobacillus* sp Dad13. There was no significant difference between the 3 types of yoghurt. Among the panelists, there was big variation in score assessment of texture. This variation may be due to low frequency of the panelists in consuming the product so that the assessment was less precise.

From Figure 3 it was shown that the highest average of flavors score was obtained in yoghurt supplemented with *Lactobacillus* sp Dad13, followed by yoghurt made with *S. thermophilus* and *L. bulgaricus*, and also yoghurt supplemented with *L. plantarum* Mut.1.

Figures must have alternative text. The sensory evaluation on flavors described in the text can be represented as follows:

![Sensory evaluation on flavors](image)

Yoghurt have to be made by a mixed starter cultures *S. thermophilus* and *L. bulgaricus* because both cultures were giving a good appearance, texture, and flavors properties (Tamine And Robinson, 1985). Fermented milk with only *Lactobacillus* sp Dad13 could be made, but the incubation period was long and the product quality was less satisfactory.

Since some probiotic strains grow very slowly in milk, traditional yoghurt cultures (*L. bulgaricus* or *S. thermophilus*) or mesophilic mixed strain culture are often used together with probiotic strains to speed up the acidification process (Dave and Shab, 1997).

We conducted co-culture experiment to study whether *Lactobacillus* sp Dad13 could compete and survive if it was grown with *S. thermophilus* and *L. bulgaricus*. From Table 3 it was seen the increasing lactic acid production, pH, and increasing bacteria population after 18 h incubation. Mixed cultures of *S. thermophilus* and *L. bulgaricus* capable of yielding higher acid production compared to others. Sensory evaluation was correlated with the result in which yoghurt made with mixed cultures of *S. thermophilus* and *L. bulgaricus* yield the highest flavor score. Total lacto-

Table 3. The percentage of lactic acid production, pH, and LAB count before and after incubation at 37 °C for 18 h.
CONCLUSION

Supplementation of traditional yoghurt with indigenous probiotic Lactobacillus sp Dad13 produced sensorically acceptable yoghurt and did not significantly different with traditional yoghurt on appearance, texture, flavors, and overall properties. It also did not statistically different on lactic acid production, pH, and LAB count. Supplementation of probiotic bacteria is important to make yoghurt as better functional food.
